Updated exposure-response functions available for estimating mortality impacts

Updated long-term effects of PM_{2.5} on natural mortality. 14 studies

PM_{2.5} (10 μg/m³ increase) and Natural Mortality

Lung Cancer and PM2.5 Meta-Analysis

Hamra G et al. EHP 2014 (under revision)

Comparison of the PM_{2.5} and NO₂ effects in the same studies (per 10 µg/m³ and IQR)

Table 2. Pooled* effects of NO₂ and PM (10 µg/m³ and IQR µg/m³) on natural and specific-cause mortality

	total or natural mortality					cardio-vascular mortality					respiratory mortality				
	N studies	RR	95% CIs	I ²		N studies	RR	95% CIs	I ²		N studies	RR	95% CIs	I ²	
NO ₂ (10µg/m3)	10**	1.040	1.015 1.065	91%		NO ₂ (10µg/m3)	15^§°	1.152 1.094 1.213	98%		NO ₂ (10µg/m3)	7#++	1.024 1.010 1.038	0%	
NO ₂ (14.6 µg/m3)		1.059	1.022 1.096			NO ₂ (17.9 µg/m3)		1.288 1.174 1.413			NO ₂ (15.0 µg/m3)		1.036 1.015 1.058		
PM _{2.5} (10 µg/m3)	9**+	1.050	1.024 1.078	78%		PM _{2.5} (10 µg/m3)	14^§°+	1.228 1.084 1.39	98%		PM _{2.5} (10 µg/m3)	6#+++	1.062 1.022 1.104	11%	
PM _{2.5} (5.8 µg/m3)		1.029	1.014 1.045			PM _{2.5} (7.0 µg/m3)		1.155 1.058 1.259			PM _{2.5} (7.0 µg/m3)		1.043 1.015 1.072		

Conclusions

- **Larger evidence base strengthens knowledge on $PM_{2.5}$ effects on mortality**
- **Linear increases in relative risks for mortality from all-natural causes, CVD, respiratory disease and lung cancer over the range of $PM_{2.5}$ in Europe and North America**
- **Independent effects of NO_2 of similar size to $PM_{2.5}$**

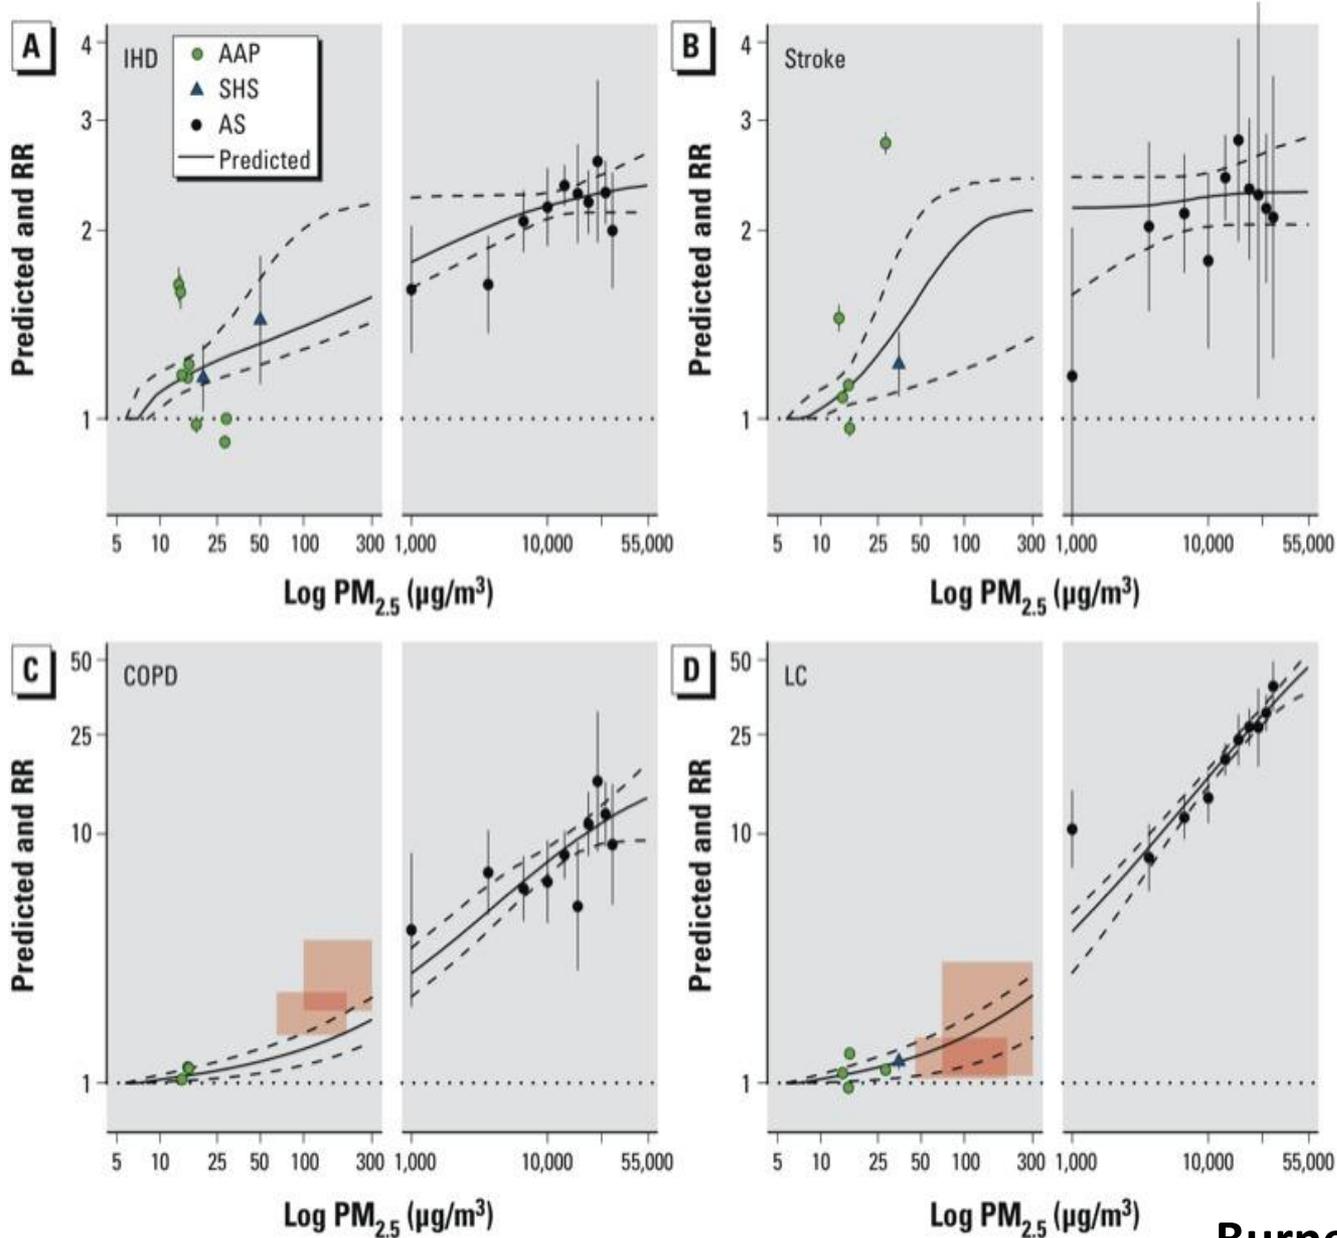

Integrated Exposure-Response (IER) Function for Particulate Matter

- **Rationale:** Most available PM_{2.5} cohort studies are conducted in the US and Europe, but it is questioned whether the cohort findings from low air pollution exposure settings in developed countries are applicable to other, more polluted parts of the world
- **Objective:** to inform the risk estimates across the full range of PM_{2.5} concentrations world wide
- **Method:** integrate evidence on mortality risk due to PM_{2.5} from other combustion sources (second-hand smoke, household burning of solid fuels, active smoking) with risk from ambient PM_{2.5} to estimate risks in highly polluted settings
- **Adopted** in the Global Burden of Disease (GBD) 2010 project
- **Details:** Burnett et al, 2014, EHP

Assumptions and Key Features of IER

- **PM_{2.5} exposure from diverse sources is associated with increased death risks from IHD, stroke, COPD, and LC, and with increased incidence of ALRI**
- **Health effects of PM_{2.5} related with inhaled mass (exposure) only, but not with PM_{2.5} composition and sources**
- **Relationship between PM_{2.5} exposure and excess mortality not necessarily restricted to be linear**
- **The RR of mortality from exposure to AAP, SHS, HAP, and AS does not depend on the temporal nature of the PM_{2.5} exposure**
- **No interaction exists among the various PM_{2.5} exposure types for any cause of mortality**
- **Curves must fit evidence for ambient air pollution at the low end and evidence for active cigarette smoking at the high end**

IERs for Adult Mortality

Strengths and Limitations

- **Strength:** enables estimation of continuous $\text{PM}_{2.5}$ risk functions across the full range of levels all over the world
- **Limitation:** requires assumptions with which expert opinion is not in complete agreement

Summary

Background Quantification of the disease burden caused by different risks informs prevention by providing an account of health loss different to that provided by a disease-by-disease analysis. No complete revision of global disease burden caused by risk factors has been done since a comparative risk assessment in 2000, and no previous analysis has assessed changes in burden attributable to risk factors over time.

Methods We estimated deaths and disability-adjusted life years (DALYs; sum of years lived with disability [YLD] and years of life lost [YLL]) attributable to the independent effects of 67 risk factors and clusters of risk factors for 21 regions in 1990 and 2010. We estimated exposure distributions for each year, region, sex, and age group, and relative risks per unit of exposure by systematically reviewing and synthesising published and unpublished data. We used these estimates, together with estimates of cause-specific deaths and DALYs from the Global Burden of Disease Study 2010, to calculate the burden attributable to each risk factor exposure compared with the theoretical-minimum-risk exposure. We incorporated uncertainty in disease burden, relative risks, and exposures into our estimates of attributable burden.

Findings In 2010, the three leading risk factors for global disease burden were high blood pressure (7.0% [95% uncertainty interval 6.2–7.7] of global DALYs), tobacco smoking including second-hand smoke (6.3% [5.5–7.0]), and alcohol use (5.5% [5.0–5.9]). In 1990, the leading risks were childhood underweight (7.9% [6.8–9.4]), household air pollution from solid fuels (HAP; 7.0% [5.6–8.3]), and tobacco smoking including second-hand smoke (6.1% [5.4–6.8]). Dietary risk factors and physical inactivity collectively accounted for 10.0% (95% UI 9.2–10.8) of global DALYs in 2010, with the most prominent dietary risks being diets low in fruits and those high in sodium. Several risks that primarily affect childhood communicable diseases, including unimproved water and sanitation and childhood micronutrient deficiencies, fell in rank between 1990 and 2010, with unimproved water

Mortality impacts from air pollution in a Comparative Risk Assessment context

- **Many public health and policy decisions require that the mortality attributable to ambient air pollution be considered in the context of mortality due to other major health risk factors**
- **CRA provides a way to provide comparable estimates for the various risk factors, but requires that consistent approaches be used to estimate risks for each**
- **By applying a common PM_{2.5} exposure metric the IER provided internal consistency among estimates for the various combustion-related risk factors, and enabled estimation of the burden of cardiovascular mortality attributable to HAP**
- **Current estimates assume that air pollution-attributable mortality is independent of other risk factors and more research is needed to address this issue**
